

Experience in using the equipment of the IMEDIS Center in the diagnosis and treatment of trichinosis, dermatomycosis, chorea, viral hepatitis (cases from practice)

N.P. Staritskaya

(medical center "Bioresonance", Minsk, Belarus)

I am a pediatrician with 28 years of experience. Currently, I work in an infectious diseases hospital and in the center of information medicine "Bioresonance". My practical use of diagnostic and therapeutic techniques - autonomic resonance test (ART), bioresonance therapy (BRT) - is five years. The work is carried out at the APK "IMEDIS-EXPERT". During this period of time, about a thousand patients passed through my hands. It can be unambiguously concluded that this method of diagnosis and treatment is one of the most effective and promising methods of diagnosis and treatment of a wide variety of diseases. Unfortunately, our data are not always confirmed by the methods of official medicine, since in some cases the diagnosis is made 6-7 months before the clinical and laboratory manifestation of the disease. The most important thing is the results of the treatment, which inspire optimism in the further use of these technologies. I will not dwell on the algorithms for diagnosis and treatment, but I will share the most interesting cases from practice associated with certain etiological factors.

So, the amazing cases associated with trichinosis.

1) Patient T., 36 years old. From the anamnesis: within three years, there have been severe pain in the heart, girdle pain in the abdomen, pain in the lumbar region, which occur cyclically and intensify towards night. Examination and treatment in a hospital, polyclinic did not give a positive effect. The final diagnosis is in favor of osteochondrosis, cardioneurosis, gastrointestinal dysfunction. The patient was in despair! In the course of ART, the presence of trichinosis with lesions of the thoracic and lumbar plexuses was revealed, which quite logically explained the clinical picture of the disease. Targeted treatment (exogenous, endogenous BRT) gave excellent results, leading to recovery. Follow-up for two years - no relapse.

2) Patient R., 38 years old. From the anamnesis: for two years, severe pain in belly, encircling in nature. Long-term examination and treatment in the gastroenterology department gave little short-term relief. Clinical diagnosis - chronic latent pancreatitis (all tests are normal). The prescribed diet led to weight loss, but did not affect the pain, which persisted and intensified towards night. At the time of the examination, in front of me is an unhappy woman who has lost hope of recovery. An examination using the ART method - trichinosis, the affected area is the lumbar plexus. The result of our treatment is recovery.

3) Patient Sh., 35 years old. From the anamnesis: for seven years, the skin tuberosity faces. Bumps of various sizes with constant alternate opening and release of an incomprehensible mass with white threads, bleeding. After the painful release of the discharge, gaping holes remain, which are closed with a plaster, followed by applying makeup. The face is swollen, the features are blurred, the look is sad, hopeless. Seven years of "tormenting" (dermatologists, cosmetologists), treatment, did not give any result. By

the results of ART - trichinosis. The affected area is the skin. Complex treatment - endogenous and exogenous BRT, enzyme therapy yielded results - this is the patient's return to life! Now she is a beautiful woman with residual scars on her face, we continue to work.

You can write a lot about trichinosis, these cases are the most striking examples. All patients were examined, they were given various diagnoses, but no one had a question about trichinosis, and only with the help of this diagnosis it became possible to make the correct diagnosis and help people.

Now from the life of dermatomycosis. When examining a patient with skin problems who was exposed to psoriasis, I was surprised that ART does not give a positive answer to this test. A chronic process in the skin caused by epidermophyton fungi is being tested. The treatment gave a positive result - slowly but surely the skin was cleared. After the "elimination" of the fungus, ART begins to test the presence of psoriasis, and now more targeted treatment is carried out aimed at this problem. In the first patient, the skin gradually cleared up, and the long-term problem ceased to bother her. Life goes on, and more than one psoriasis has "passed through my hands." The repetition of cases leads to a pattern. In all, at the beginning of the diagnosis, a fungal infection of the skin is tested, with the cure of which a significant improvement occurs in some patients, and in some, after improvement, exacerbation again, but the etiological factor is completely different - it is a follicular mite! We work further and get a positive result. Here is the answer to the question why psoriasis is not treated? Because there is no comprehensive approach to the treatment of this pathology, the etiological factor is not taken into account! And only thanks to these technologies, it is possible to solve many "unsolvable" problems.

Over the past year, a meeting with an "old friend" - beta-hemolytic streptococcus has become more frequent. Unfortunately, the practitioner often becomes a hostage to the classic clinic of many diseases. Often erased forms go unnoticed, are not confirmed by laboratory. In my practice, there are several children who have been treated for "neurosis-like tics" with an illness experience of three to seven years. An ART examination revealed a chronic process in the motor area of the brain caused by beta-hemolytic streptococcus! Chorea! Laboratory data in children were within normal limits, which did not allow doctors to suspect the presence of an infectious process. The mother of the boy, who had been ill for six years, had undergone several inpatient treatments, was very skeptical about the diagnosis. Without faith in her eyes, she said: "If everything were so easy, everyone would be healthy!" Three months later, my mother made a speech in a completely different tone, for which I am grateful. I quote her words: "Doctor, I did not believe these technologies, I believed that, believing, I could pass off what I wanted as reality. I strictly followed all the recommendations and, regardless of my opinion, my son recovered! Thanks!" Examination of the boy in a year is healthy. Another example is the same process, but in adults (4) and the clinic is more serious, the diagnosis is the sentence - epilepsy! Complex targeted treatment gives a lasting positive result.

I have also obtained good results in the treatment of viral hepatitis. Naturally, as an infectious disease doctor who identified this pathology, I send the patient for laboratory examination. Unfortunately, our official medicine cannot make a diagnosis at an early stage.

diseases. In my practice, there have been several cases when, after detecting HBV, sending patients for examination, I did not receive confirmation of the diagnosis. Patient confidence declined, and treatment was discontinued, despite the continuation of this process during follow-up testing. Seven months later, they returned due to a deterioration in their condition and health, the appearance of changes in biochemical blood tests, changes in the liver during ultrasound, but markers of viral hepatitis were not obtained! According to the results of ART - the progression of the HBV process. Good results were obtained after the treatment was carried out. Examination after six months - no complaints or problems.

I would like to write more about a very interesting case. Girl, 7 years old - one of the first patients, 2004. Complaints of parents about the child's night fears. The girl sleeps with the lights on, screams at the moment of falling asleep and then falls asleep in tears, holding her mother's hand. Both the girl and her parents are exhausted. ART is a mental load of the 8th degree! I test with Bach colors - hypersensitivity, uncertainty, fear. I ask: "What are you afraid of?" Answer: "Dinosaurs!" I asked her to draw her abuser. A terrible image of the real Serpent Gorynych appeared in front of me! The girl put all the horror into this drawing, and she is studying at an art school. Conducted by the Institute for Applied Mathematics "Detskaya", OBRT against the background of selected Bach flowers and the pattern of "Gorynych" in the inverse container of the apparatus. Two weeks later, the happy mother was surprised at the changes in her daughter, the improved sleep. Girl, listening to the conversation, he says in a clear voice: "Aha, mommy, I'm still afraid of dinosaurs!" "Draw!" The girl draws and laughs. It was not a dinosaur that appeared before my eyes, but Ryaba's chicken! We started laughing together.

In 2009, the girl congratulated me on the New Year - she gave me a watercolor painting. The magnificent lilac shone with bright, joyful colors.

You can write endlessly about your work. It is happiness when you can help people, and you do it!
